Run Stable Diffusion on your M1 Mac's GPU

Posted August 31, 2022 by @bfirsh

Stable Diffusion is open source, so anyone can run and modify it. That's what has caused the abundance of creations over the past week.

You can run Stable Diffusion in the cloud on Replicate, but it's also possible to run it locally. Generating predictions, you can hack on it, modify it, and build new things. Getting it working on your Mac's GPU is a little fiddly, so we've created this guide to show you how to do it.

All credit for this goes to everyone who contributed to this fork of stable-diffusion on GitHub. We figured it all out in [this GitHub thread](#). We're merely messengers of their great work.

One thing we've done on top of previous work: use pip instead of Conda to install dependencies. It's much easier to set up and shouldn't need to compile anything because it uses binary wheels.

How to Run a ChatGPT-type LLM on Your Own Hardware

 Xanny.eth · 0x8952 · March 25th, 2023

 1 Collected 

Running a Large Language Model (LLM) on your own laptop can be an intimidating prospect, but it doesn't have to be. With the right tools and techniques, you can make it work. In this post, we will explore the various options available for running large

The background is a dark, deep blue. It is filled with numerous glowing, out-of-focus circles in shades of cyan and light blue, creating a bokeh effect. On the left side, there are several thin, bright blue lines that appear to be fiber optics or light trails, some of which have small, sharp points of light at their ends. A few larger, more saturated red circles are also visible, particularly on the left side, adding a contrasting color to the predominantly blue palette.

Die Zukunft bleibt spannend!
